

$^{36}\text{Ar}(^3\text{He},\alpha)$ **1973Be26**

$J^\pi=0^+$ for ^{36}Ar ground state.

1973Be26: An 18-MeV ^3He beam was produced by the University of Pennsylvania tandem Van de Graaff accelerator. The target was pure argon gas enriched to 99.8% in ^{36}Ar . α particles were momentum analyzed in a multi-angle spectrograph and detected using Ilford K-1 nuclear emulsions with FWHM=35 keV. Measured $\sigma(E_\alpha, \theta)$. Deduced levels, J, π , L-transfers, and spectroscopic factors from local zero-range DWUCK-DWBA analysis of the measured $\sigma(\theta)$. Comparisons with shell-model calculations and the mirror nucleus ^{35}Cl . Also see **1972MiZO**.

 ^{35}Ar Levels

Spectroscopic factor $C^2S=(2j+1)\times\sigma(\theta)_{\text{exp}}/\sigma(\theta)_{\text{DWBA}}/N$, where the isospin Clebsch-Gordan coefficient C^2 is 1/2 in this case, j is the total angular momentum of the transferred neutron, and the normalization factor $N=16.8$. **1973Be26** states that the overall normalization for the $(^3\text{He},\alpha)$ reaction is not well determined and therefore resort to empirical means to determine N. $N=15.5$ deduced from shell-model calculated total $S=3.52$ for all four $1/2^+$ states and the **1973Be26** measured $NS=54.6$. $N=18.1$ deduced from the $^{35}\text{Cl}(^3\text{He},d)^{36}\text{Ar}(\text{g.s.})$ $S=4.73$ (**1970Mo10**) and the **1973Be26** measured $^{36}\text{Ar}(^3\text{He},\alpha)^{35}\text{Ar}(\text{g.s.})$ $NS=85.4$. **1973Be26** adopted the average $N=16.8$.

[†] As given in **1973Be26**, also used for extracting C^2S .

 $^{36}\text{Ar}(^3\text{He},\alpha)$ [1973Be26](#) (continued)

 ^{35}Ar Levels (continued)

[‡] Converted from the S values in [1973Be26](#) with $C^2=1/2$.

[#] [1973Be26](#) states that the differences for $j=3/2$ and $5/2$ are small in the DWBA-calculated $L=2$ shapes. It is not possible to differentiate between the two allowed j values for $L=2$ transitions. Both C^2S values are given for each level with two spin values. Assuming that all four levels have spins of $3/2$ would lead to a summed $L=2$ C^2S that exceeds the simple shell-model sum rule limit of 8 for combined $1d_{3/2}$ and $1d_{5/2}$ pickup, which suggests that all four of these levels probably have $5/2^+$.
