^{35}K $\varepsilon+\beta^+$ decay (175 ms) 1980Ew02

Parent: ^{35}K: E=0; $J^\pi=3/2^+$; $T_{1/2}$=175 ms *2*; Q(ε)=11874.4 *9*; %ε+%β^+ decay=100

^{35}K-J^π,$T_{1/2}$: From the Adopted Levels of ^{35}K.

^{35}K-$T_{1/2}$: Weighted average of 175 ms *2* (2018Sa54), 178 ms *8* (1998Sc19), and 190 ms *30* (1980Ew02).

^{35}K-Q($\varepsilon+\beta^+$): From 2021Wa16.

^{35}K-%($\varepsilon+\beta^+$)p=0.37 *15* for E(p)>0.9 MeV (1980Ew02). E(p)<0.9 MeV has also been observed (2018Sa54,2019ChZU).

1980Ew02,1979Ca15: A 600-MeV proton beam was produced from the synchrocyclotron at CERN-ISOLDE and bombard a ScC_2 target. The ^{45}Sc(p,8n3p) spallation reaction products diffused out of the target and reached a tungsten surface ionization source where potassium isotopes were selectively ionized. The beam was extracted from the ion source, separated by the ISOLDE analyzing magnet, and collected by a mylar foil for γ-ray measurements and then a carbon foil for proton measurements. γ rays were detected using a Ge(Li) detector. Time for positron activities were determined using a 700−μm thick silicon detector. Protons were detected using a 20−μm-700−μm thick ΔE-E telescope of silicon surface barrier detectors with FWHM=50 keV. Measured Eγ(<5 MeV), Iγ, E_p(>0.9 MeV), I_p. Deduced Deduced levels, J, π, decay branching ratios, log *ft*, parent ^{35}K $T_{1/2}$, and coefficients of the isobaric multiplet mass equation for A=36, T=2 quartets. Comparisons with shell-model calculations and the mirror nucleus ^{35}Cl. Also see abstracts 1978HaYH, 1979HaZY, 1979HaZT, and 1979AnZZ.

2018Sa54: A 36-MeV/nucleon ^{36}Ar primary beam was produced from the K500 cyclotron at Texas A&M University. The secondary ^{35}K beam was produced via the $^1H(^{36}Ar,^{35}K)2n$ reaction of ^{36}Ar bombarding a LN_2-cooled hydrogen gas target, separated by MARS, and implanted into a 45−μm DSSD sandwiched between a 140−μm SSSD and a 1-mm Si-pad detector in a pulsed-beam mode. $\varepsilon+\beta^+$-delayed protons were detected by the implantation detector. γ rays were detected by two HPGe detectors. Measured E_p(>300 keV), I_p, Eγ, Iγ, pγ-coin, $\gamma\gamma$-coin. Deduced parent ^{35}K $T_{1/2}$.

2019ChZU: Same beam production as 2018Sa54. ^{35}K was implanted into the AstroBox2 detector filled with 800-Torr P5 gas. $\varepsilon+\beta^+$-delayed protons were detected by the implantation detector. γ rays were detected by 4 Clover Ge detectors. Measured E_p(>100 keV), I_p, Eγ, Iγ, pγ-coin, $\gamma\gamma$-coin.

1998Sc19: A polarized ^{35}K beam was produced via the fragmentation of 500-MeV/nucleon ^{40}Ca impinging on a ^9Be target at GSI, separated using ΔE-tof by FRS, momentum-selected by slits, and implanted into a KBr single crystal placed in the central region of a magnet. Positrons were detected using plastic scintillators. γ rays were detected using a Ge detector. Measured β-decay asymmetry and $\beta\gamma$-coin. Deduced polarization and *g*-factor of ^{35}K ground state from β-NMR and ^{35}K $T_{1/2}$ from $\beta\gamma$-decay time spectra.

2006Me04: A polarized ^{35}K beam was produced via the proton-pickup reaction $^{36}Ar(^9Be,^{10}Li)^{35}K$, separated by NSCL-A1900, and implanted into a KBr crystal. Positrons were detected using plastic scintillators. Deduced the magnetic dipole moment and *g*-factor of ^{35}K ground state from β-NMR.

Theoretical studies involving ^{35}K decay: shell model (1985Br29, 2003Sm02).

† Absolute intensity per 100 decays.

^{35}K $\varepsilon+\beta^+$ decay (175 ms) 1980Ew02 (continued)

$\gamma(^{35}Ar)$

Iγ normalization: From Σ%Iγ(γ to g.s.)=80.6 *40*, deduced from 100−Σ%I$_p$-%I($\varepsilon+\beta^+$)(g.s.), where Σ%I$_p$=0.37 *15* (1980Ew02) and %I($\varepsilon+\beta^+$)(g.s.)=19 *4* (1980Ew02), corresponding to log *ft*=5.07 *5*, which was deduced from the ^{35}S (g.s.)->^{35}Cl (g.s.) mirror log *ft*=5.01 *2* with a small asymmetry correction.

$\varepsilon+\beta^+$ feeding is obtained from γ intensity balance at each level. 1980Ew02 states that in complex decay schemes of heavy nuclides this method is known to be suspect since there is significant γ intensity that is unobserved because it lies in a multitude of very weak γ-ray peaks. In a nucleus as light as ^{35}K the problem is less acute. They have generated a pandemonium test in the same spirit as in 1977Ha51 and find that less than one percent of the γ intensity from ^{35}K decay should be missed for that reason.
